CSC 120 ICA-13

Work with your neighbor. (This will be graded for participation only.)

For reference, here are diagrams of a Python list and a LinkedList having the integers 10,20 and 30 as elements:

1. The LinkedList code includes a method add() for adding to the front of a LinkedList:

```
class Node:
    def __init__(self, value):
        self._value = value
        self._next = None

        def __init__(self):
        self._head = None

        def add(self, new):
        new._next = self._head
        self._head = new
```

Draw a diagram that shows the linked list alist and the node in after the statements below are executed:

```
>>> alist = LinkedList()
>>> n = Node(14)
```

Draw a diagram that shows the list  ${\tt alist}$  after the statement below is executed:

```
>>> alist.add(n)
```

Draw a diagram that shows the node n after the statement below is executed:

```
>>> n = Node(6)
```

Draw a diagram that shows the list alist after the statement below is executed: >>> alist.add(n)

node's next reference with None.

```
Note: You may draw the diagram without the box for the list head and without labelling the last
```

2. This code has a method for traversing a LinkedList to print all node values.

```
class Node:
    def __init__(self, value):
        self._value = value
        self._next = None

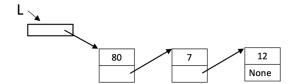

class LinkedList:
    def __init__(self):
    self._head = None

    def add(self, new):
        new._next = self._head
        self._head
        self._head = new

    def print_elements(self):
        current = self._head
        while current != None:
        print(str(current._value))
        current = current._next
        self._head = new
```

Using the LinkedList and Node class definitions above, write a method double() for the LinkedList class that doubles the value attributes of all nodes in a LinkedList. You may assume that for each node in the list, the value attribute is an integer.

3. The code in problem 2 has a method print\_elements (self) for traversing a LinkedList to print all node values. Let's go through the steps to do that for the linked list below:

When the code L.print\_elements() is called, self will refer the list L. The slides showed how to set a reference to the first element of the list, and continually change that reference to "walk" through the list. Using the variable current, what is the code to set current to the first element of the list? Show the code and draw the list with current set to the first element:

What is the code to move current forward to the next (second) node? Show the code and the resulting diagram after moving forward again:

Show the code to move current forward to the next (third) element and the diagram:

Show the code to move current forward one more time. What is the value of current is at this point?

4. (Extra.) Using the LinkedList and Node class definitions above, write a method print\_evens(self) for the LinkedList class that prints the even values of the nodes. If there are no even values, the method does not print anything. You can assume that all values in the nodes are integers.
