

# CSc 120

## Introduction to Computer Programming II

Lists (arrays) vs. Linked Lists: Complexity

performance puzzler

# Example: list insert vs append

**insert:** adds an element into the middle of a list

```
>>> list0 = [1,2,3,4]
>>> list0
[1, 2, 3, 4]
>>> list0.insert(2, 'aaa')
>>> list0
[1, 2, 'aaa', 3, 4]
>>> list0.insert(3, 'bbb')
>>> list0
[1, 2, 'aaa', 'bbb', 3, 4]
>>> |
```

**append:** adds an element at the end of a list

```
>>> list0 = [1,2,3,4]
>>> list0
[1, 2, 3, 4]
>>> list0.append('aaa')
>>> list0
[1, 2, 3, 4, 'aaa']
>>> list0.append('bbb')
>>> list0
[1, 2, 3, 4, 'aaa', 'bbb']
>>> |
```

# Example: list insert vs append

**insert:** adds an element into the middle of a list

`list0 = mklist(n)`    *# length of list0 == n*

`list0.insert(n//2, 0)` *# insert at midpoint*

**append:** adds an element at the end of a list

`list0 = mklist(n)`

`list0.append(0)` *# add at the end*

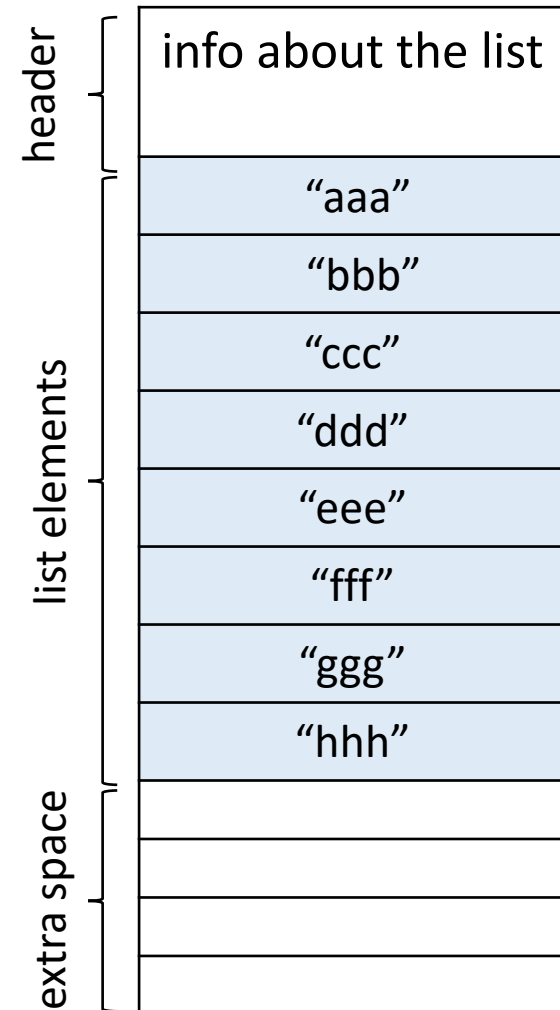

*Why this difference?*

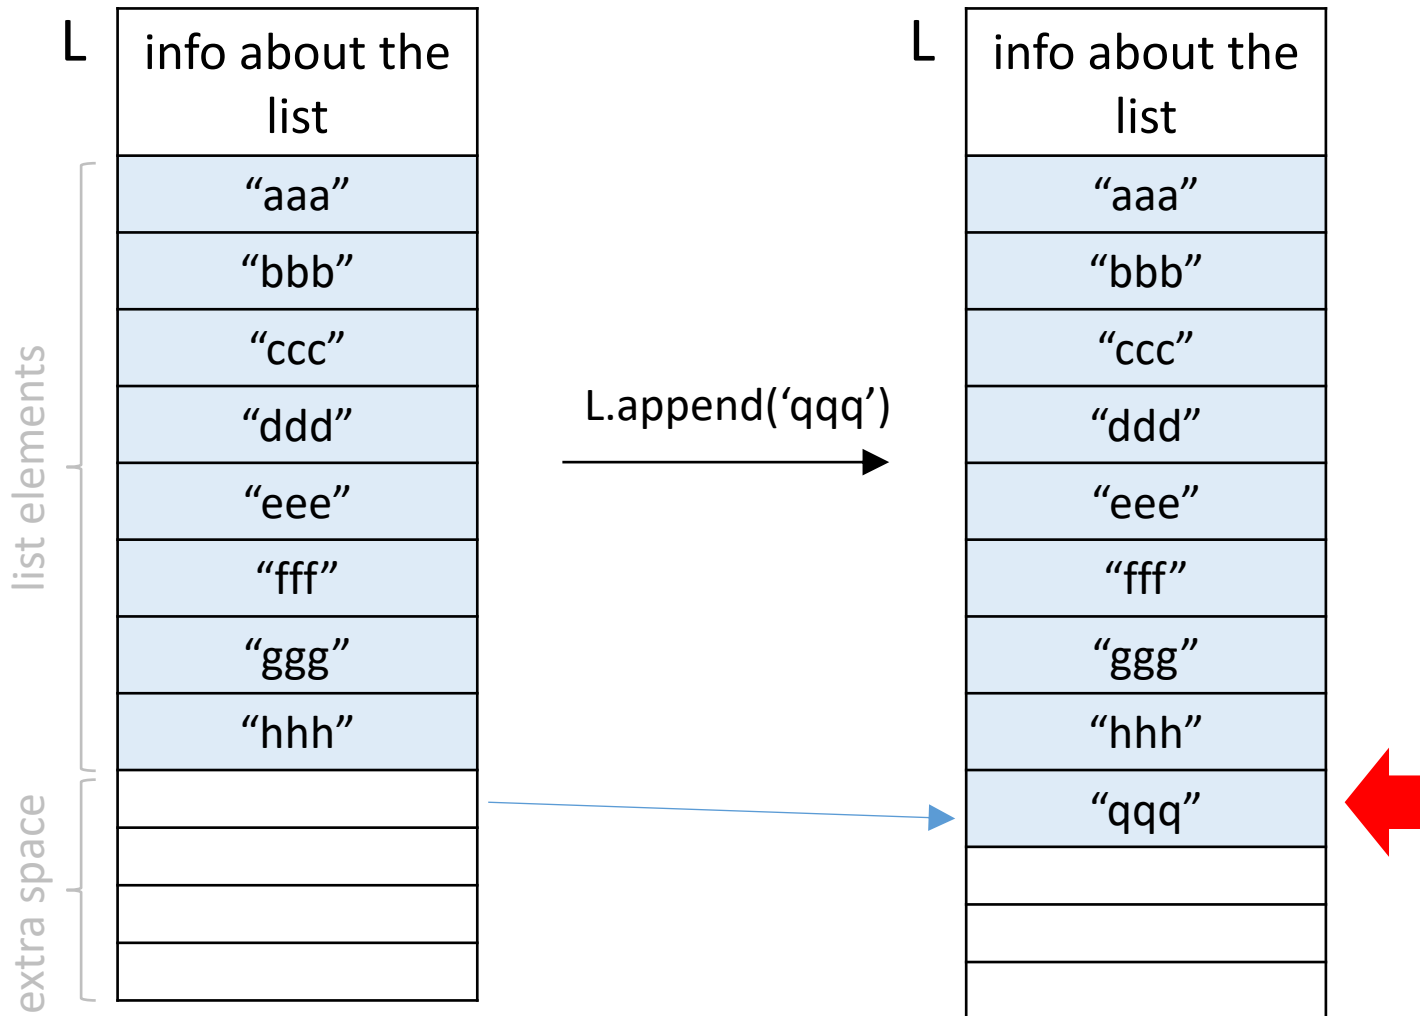

insert vs. append

# List (array) organization in Python

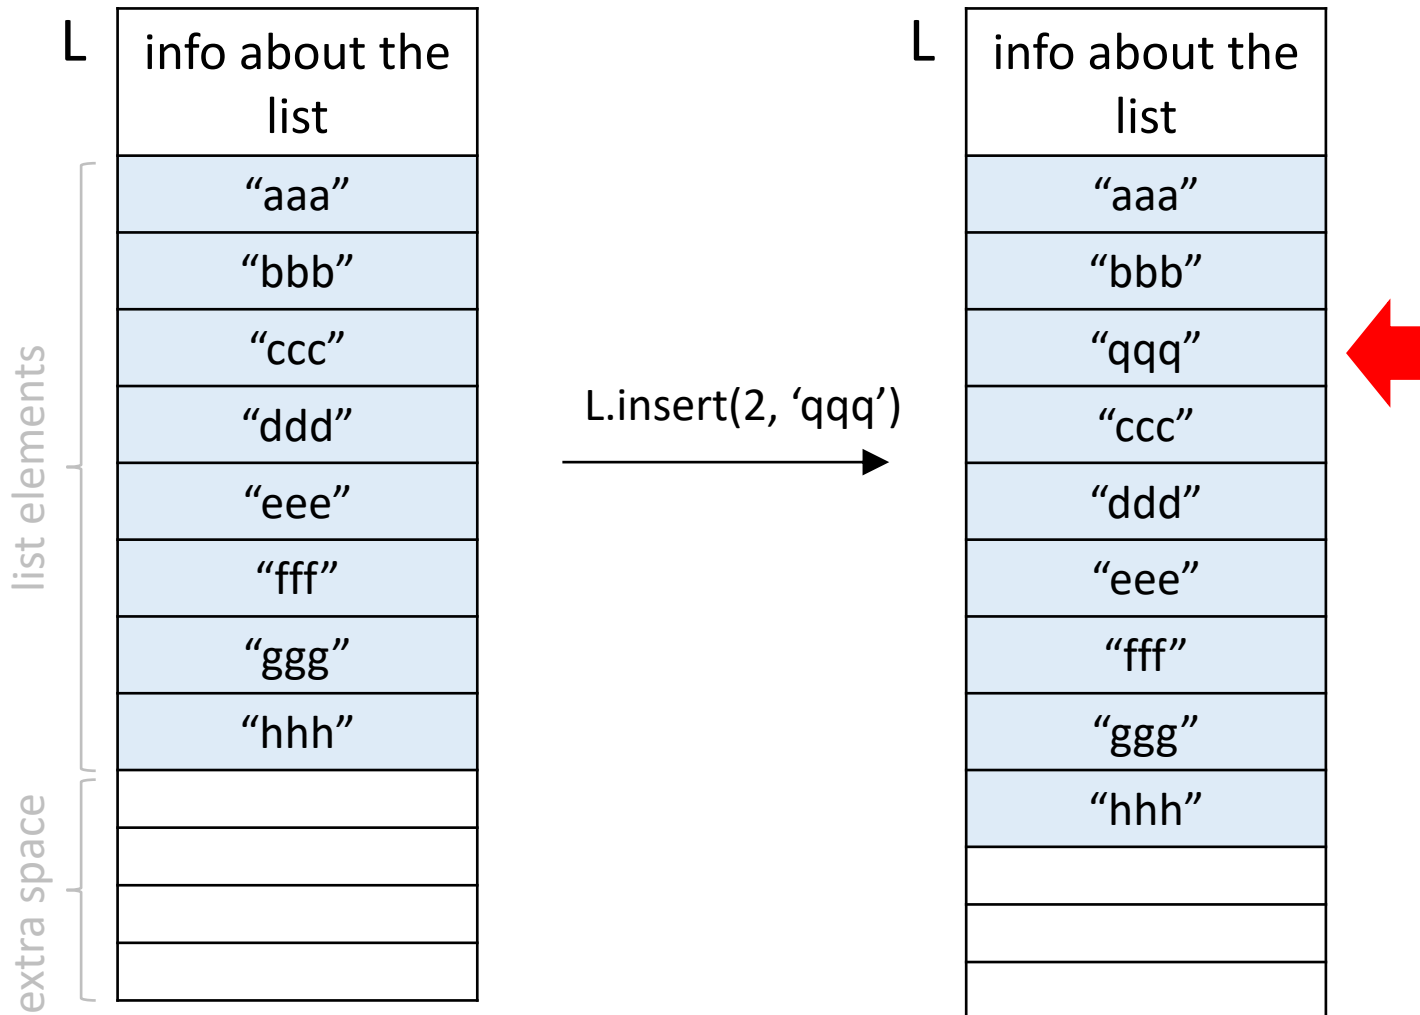

- (References to) the list elements are kept in a contiguous sequence of memory words
  - there is a little extra space at the end to give it some room to grow
- The following operations are  $O(1)$ :
  - `len()`
    - read off length info from the header
  - accessing the  $i^{\text{th}}$  element of the list
    - compute its address using the value of  $i$
    - access memory location at that address

# Appending to a list $O(1)$

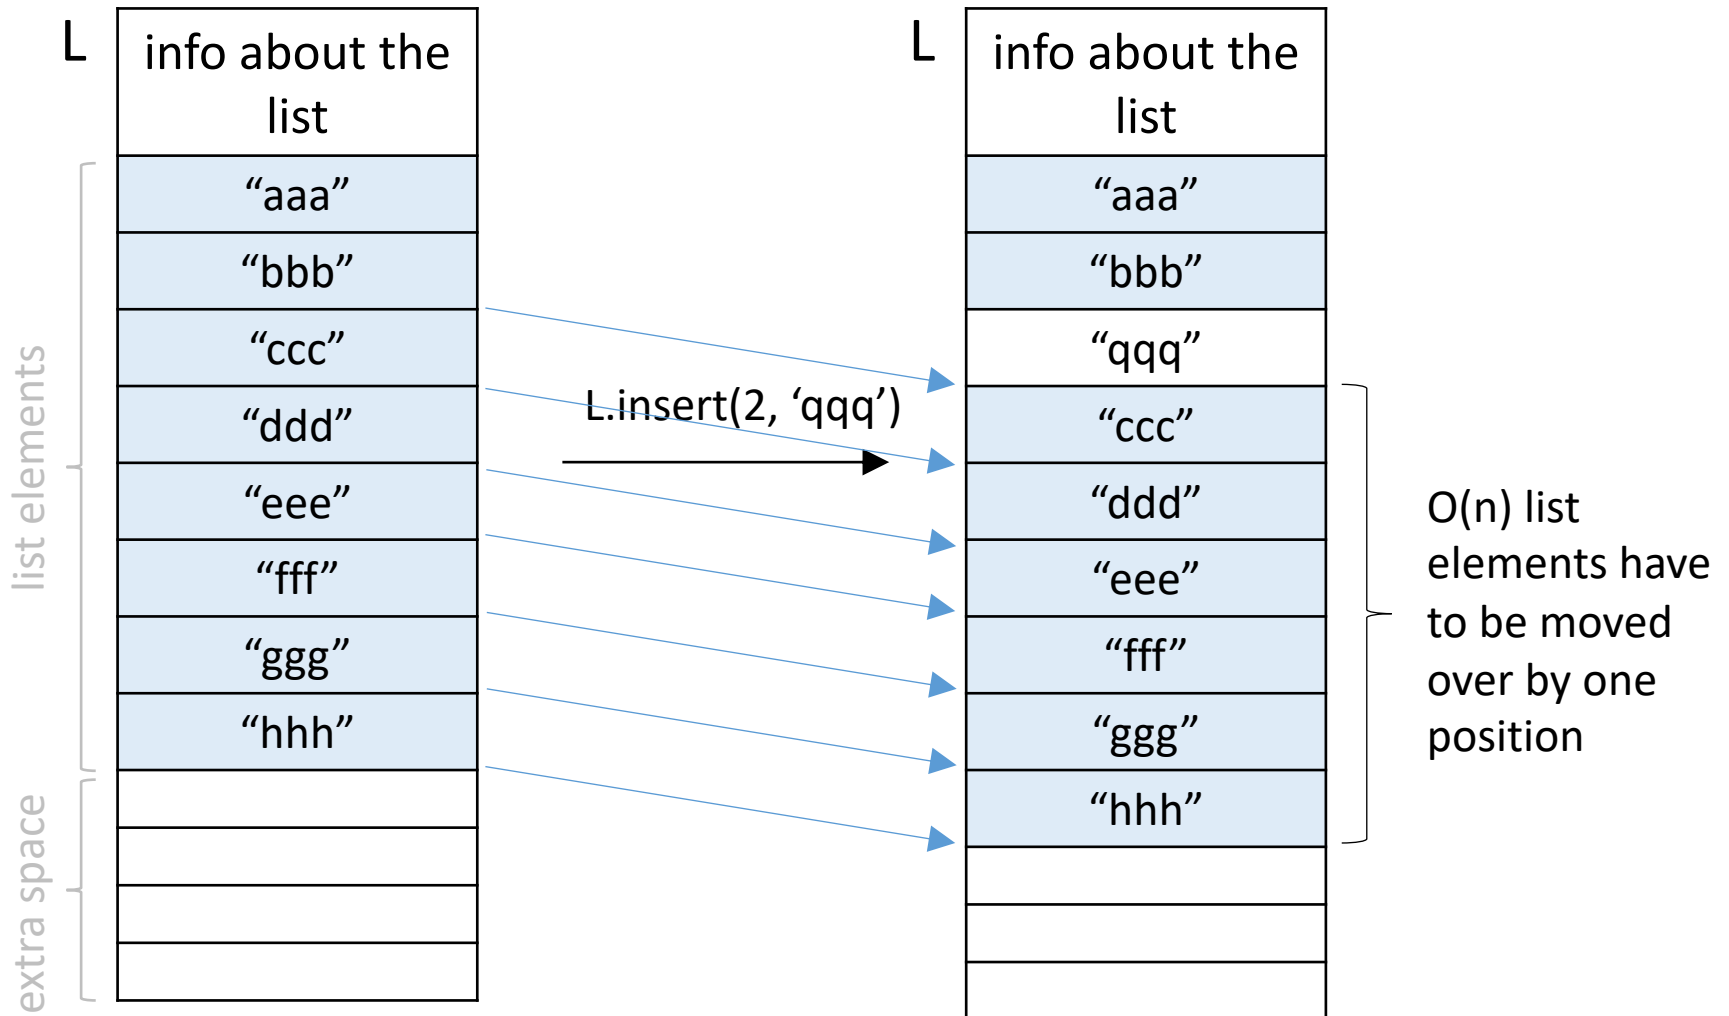

# Inserting into a list

# Inserting into a list $O(n)$

# Python lists: complexity summary

Operation	Complexity
len	$O(1)$
access an element's value	$O(1)$
append	$O(1)$
insert, delete	$O(n)$

Q: Can we do insert in  $O(1)$  time?

(The complexity of other operations may change)

# Exercise-ICA 31 Prob. 1&2

# Python lists: reprise

- Key feature:  $L[i]$  and  $L[i+1]$  are adjacent in memory
- This makes accessing  $L[i]$  very efficient
  - $O(1)$
- Insertion and concatenation require moving  $O(n)$  elements
  - $O(n)$

# Linked lists: reprise

- To get  $O(1)$  insertion and concatenation, we cannot afford to move  $O(n)$  list elements
- We have to relax the requirement that  $i^{\text{th}}$  element is adjacent to  $(i+1)^{\text{st}}$  element
  - any element can be anywhere in memory
- Each element has to tell us where to find the next element

# Linked lists

With each element of the list, keep a reference to the next list element

"nodes"

each node in the  
list has a reference  
to the next node

# Linked lists

References are addresses in memory.

Here is the diagram with explicit addresses (simplified).

# Insertion

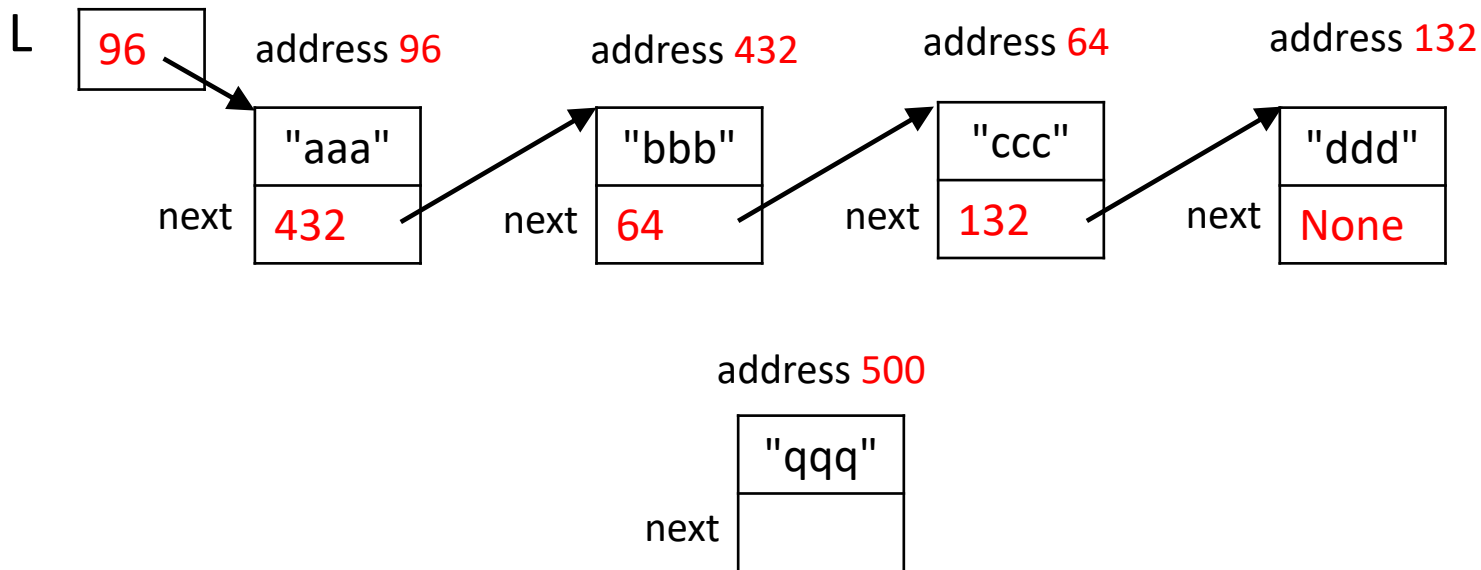

Consider inserting a new node into the linked list

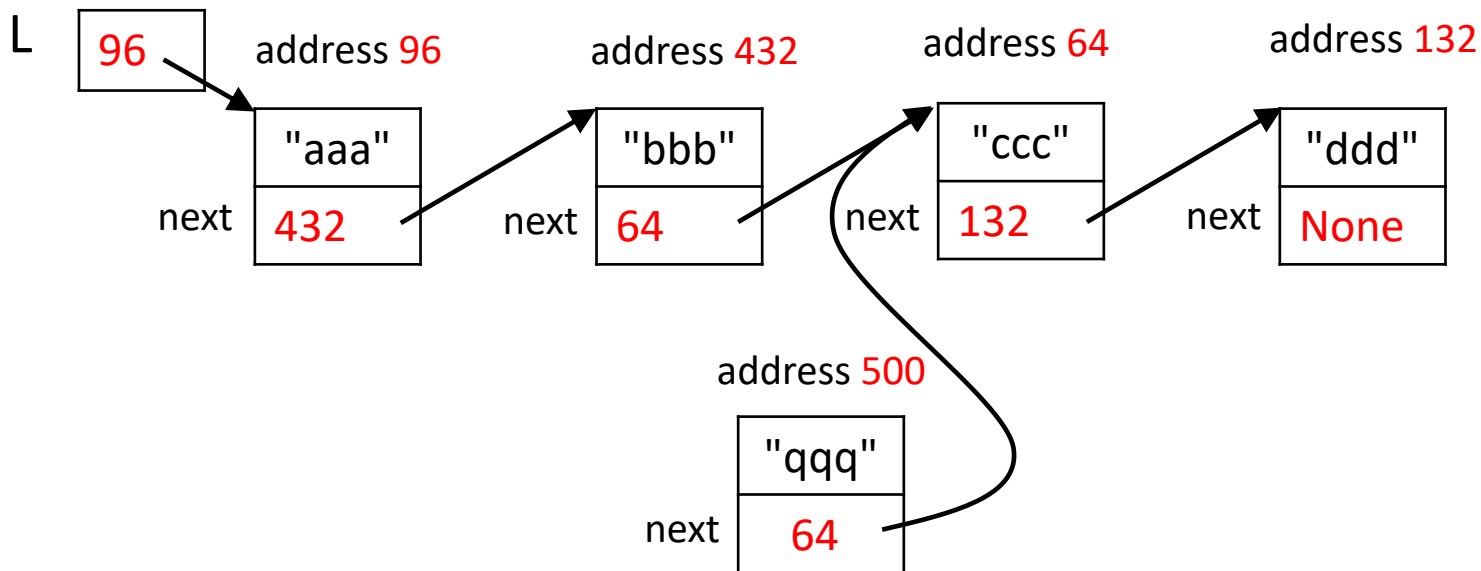

# Insertion

Specifically, add a new node between "bbb" and "ccc". What do we change?

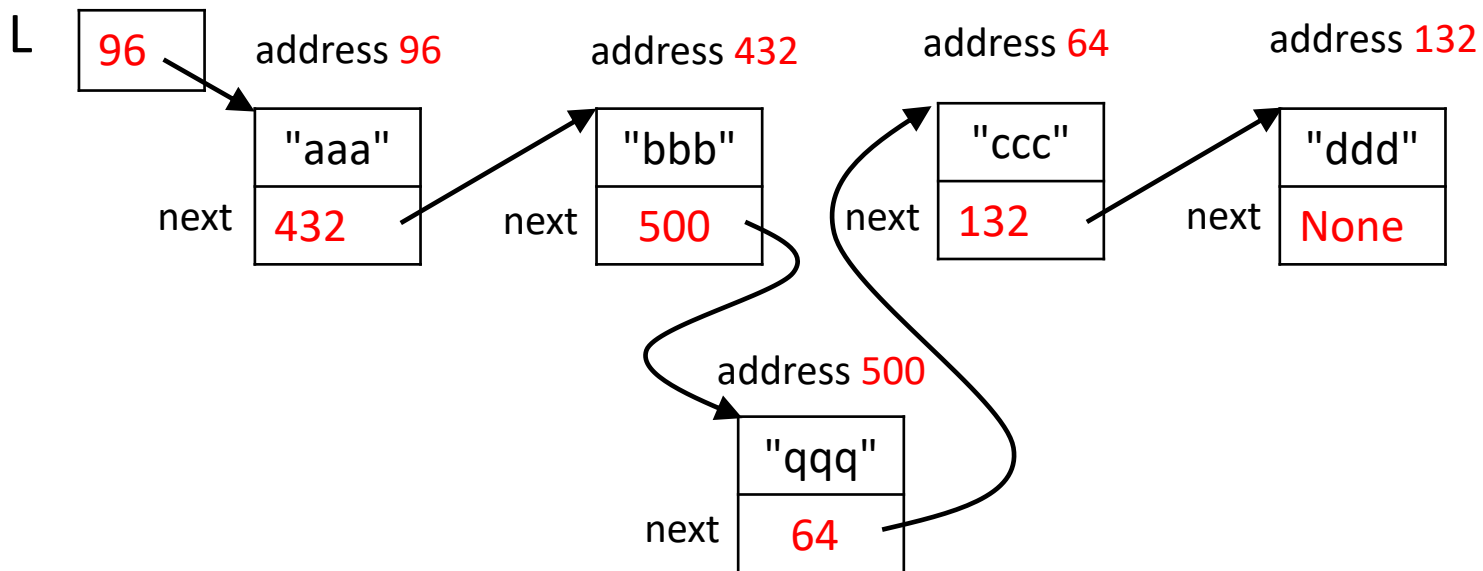

# Insertion

Specifically, add a new node between "bbb" and "ccc". What do we change?

# Insertion

We want to add a new node between "bbb" and "ccc". What do we change?

# Insertion

$O(1)^*$

Set the next references appropriately. What is the complexity of insertion?

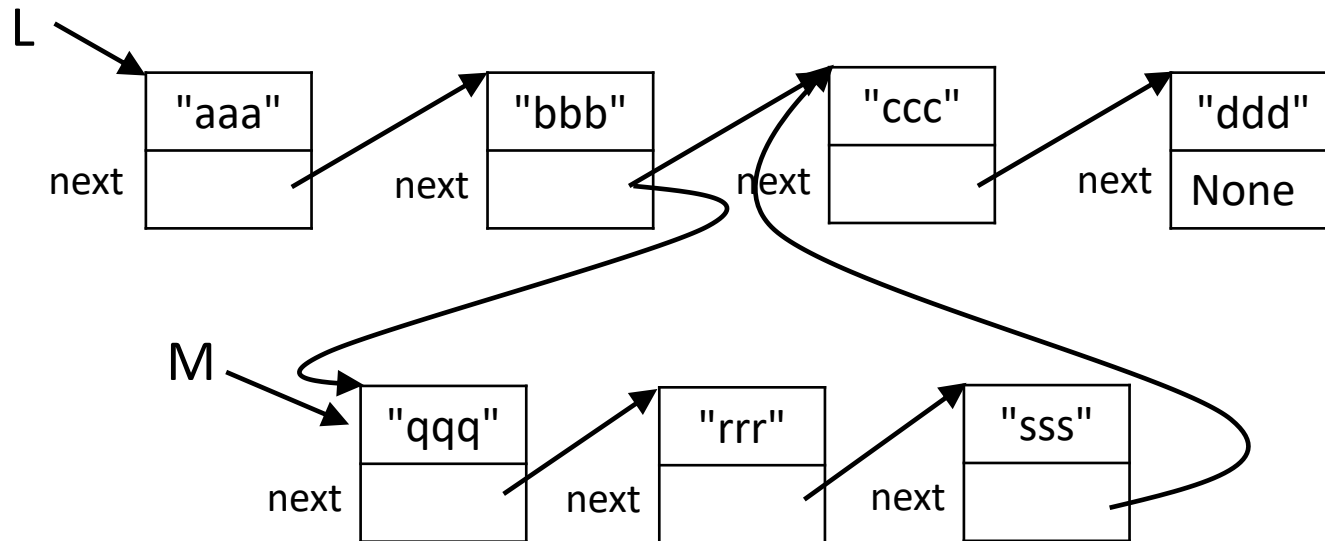

\*assuming we have a reference to the node of insertion

# Insertion

$O(1)$

To insert an element (which can be a linked list) into a linked list: set next references appropriately

# Insertion

$O(1)$

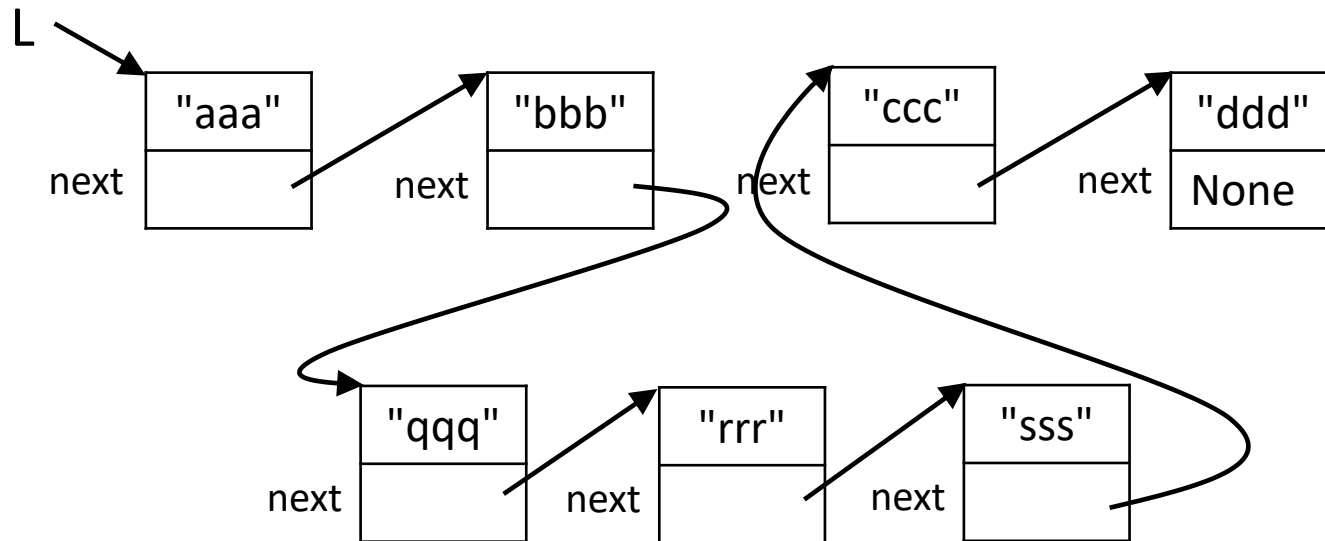

To insert an element into a linked list: set next references appropriately

# Insertion

$O(1)^*$

To insert an element into a linked list: set next references appropriately

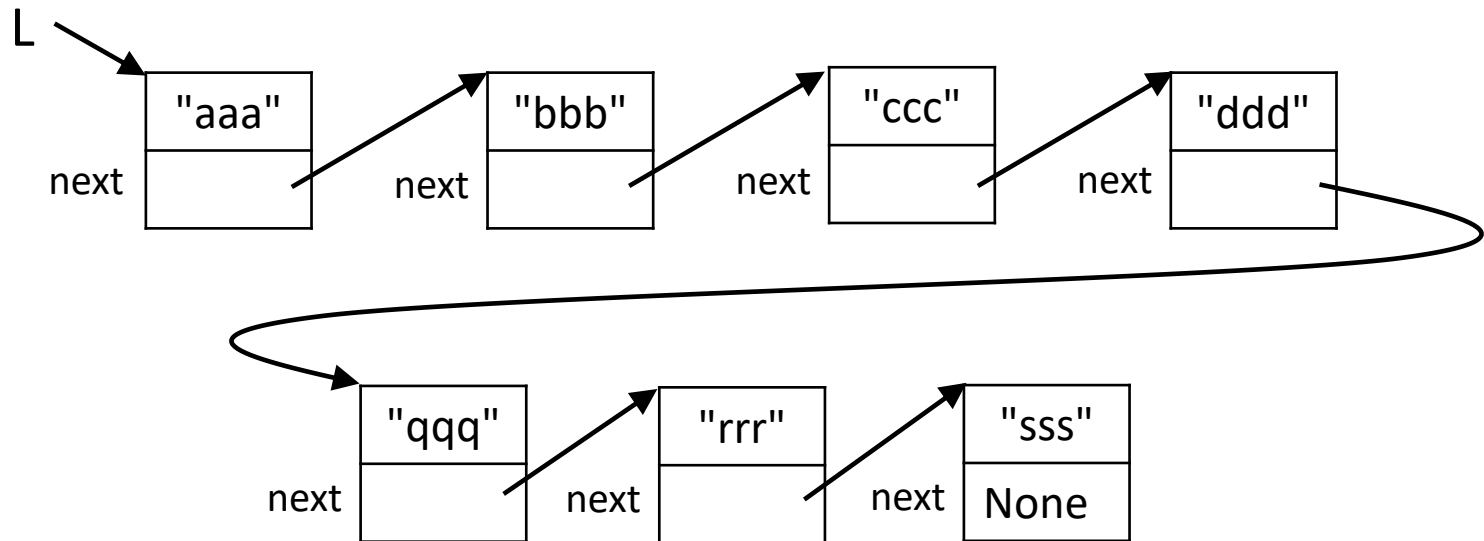

\*assuming we have a reference to the node of insertion

# Concatenation

$O(1)^*$

To concatenate two linked lists: set next reference of end of first list to refer to beginning of second list

\* once we have a reference to the end of the first list

addition  
at the head of the list

# Adding a node at the head

```
class LinkedList:
```

```
    def __init__(self):
```

```
        self._head = None
```

**$O(1)$**

*# add a node new at the head of the linked list*

```
    def add(self, new):
```

```
        new._next = self._head
```

```
        self._head = new
```

# Visiting each element

```
class LinkedList:
```

```
    def __init__(self):  
        self._head = None
```

```
    ....
```

```
    def print_elements(self):  
        current = self._head  
        while current != None:  
            print(str(current._value))  
            current = current._next
```

$O(n)$

adding to the  
end (tail) of the list

# Adding a node to the tail

To add a node `new` at the end (i.e., tail) of a list `L`:

1. find the last element `Y` of `L`
2. `Y._next = new`

# Adding a node to the tail

To add a node `new` at the end (i.e., tail) of a list `L`:

1. find the last element `Y` of `L`   $O(n)$
2. `Y._next = new`   $O(1)$

# Adding to the end

```
class LinkedList:
```

```
    def add_to_end(self, new):
```

```
        if self._head == None:      # the list is empty
            self._head = new         # the list now has one node
```

```
        else:
```

```
            current = self._head
```

```
            prev = None
```

```
            while current != None:
```

```
                prev = current      # keep track of previous node
```

```
                current = current._next
```

```
            prev._next = new         # add to the end
```

$O(n)$

finding the  $n^{\text{th}}$  element

# Finding the $n^{\text{th}}$ element

```
class LinkedList:
```

```
# return the node at position n of the linked list
```

```
def get_element(self, n):
```

```
    elt = self._head
```

```
    while elt != None and n > 0:
```

```
        elt = elt._next
```

```
        n -= 1
```

```
    return elt
```

$O(n)$

insertion

# Inserting a node

Suppose we want to insert a node X into a list here:

Then we have to adjust the next-node reference on the node Y just before that position

# Inserting a node

Suppose we want to insert a node X into a list here:

Then we have to adjust the next-node reference on the node Y **just before that position**

# Inserting a node

Inserting a node  $X$  at position  $n$  in a list  $L$ :

1. find the node  $Y$  at position  $n-1$ 
  - iterate  $n-1$  positions from the head of the list\*
2. insert  $X$  after  $Y$ 
  - adjust next-node references as in previous example

```
Y = L._head
```

```
for i in range(n-1):
```

```
    Y = Y._next
```

```
X._next = Y._next
```

```
Y._next = X
```

\* do something sensible if the list has fewer than  $n-1$  nodes

# Inserting a node

class LinkedList:

*# insert a node new at position n*

def insert(self, new, n):

if n == 0:

self.add(new)

else:

prev = self.get\_element(n-1)

new.next = prev.next

prev.next = new

$O(n)$

deletion

# Deleting a node

Suppose we want to delete this node:

# Deleting a node

Suppose we want to delete this node:

# Deleting a node

Suppose we want to delete this node:

1. find the node Y just before X }  $O(n)$   
(i.e.,  $Y\_next == X$ )
2.  $Y\_next = X\_next$  }  $O(1)$
3.  $X\_next = None$

# Deleting a node

```
class LinkedList:
```

```
    # delete a node X
```

```
    def delete(self, X):
```

```
        if self._head == X:           O(1)
```

```
            self._head = X._next
```

```
        else:
```

```
            Y = self._head
```

```
            while Y._next != X:       O(n)
```

```
                Y = Y._next
```

```
            Y._next = X._next
```

```
            X.next = None
```

# Remove from the front

Removing from the front is simpler:

# Removing a node from the front

Removing from the front is simpler:

$O(1)$

concatenation

# Exercise-ICA 31 Prob. 3

```
class LinkedList:
```

```
    # concatenate list2 at the end of the list
```

```
    def concat(self, list2):
```

maintaining a tail  
reference

# Maintaining a tail reference

A variation is to also maintain a reference to the tail of the list

## LinkedList

```
class LinkedList:
```

```
    def __init__(self):
```

```
        self._head = None
```

```
        self._tail = None
```

# Tail references and concatenation

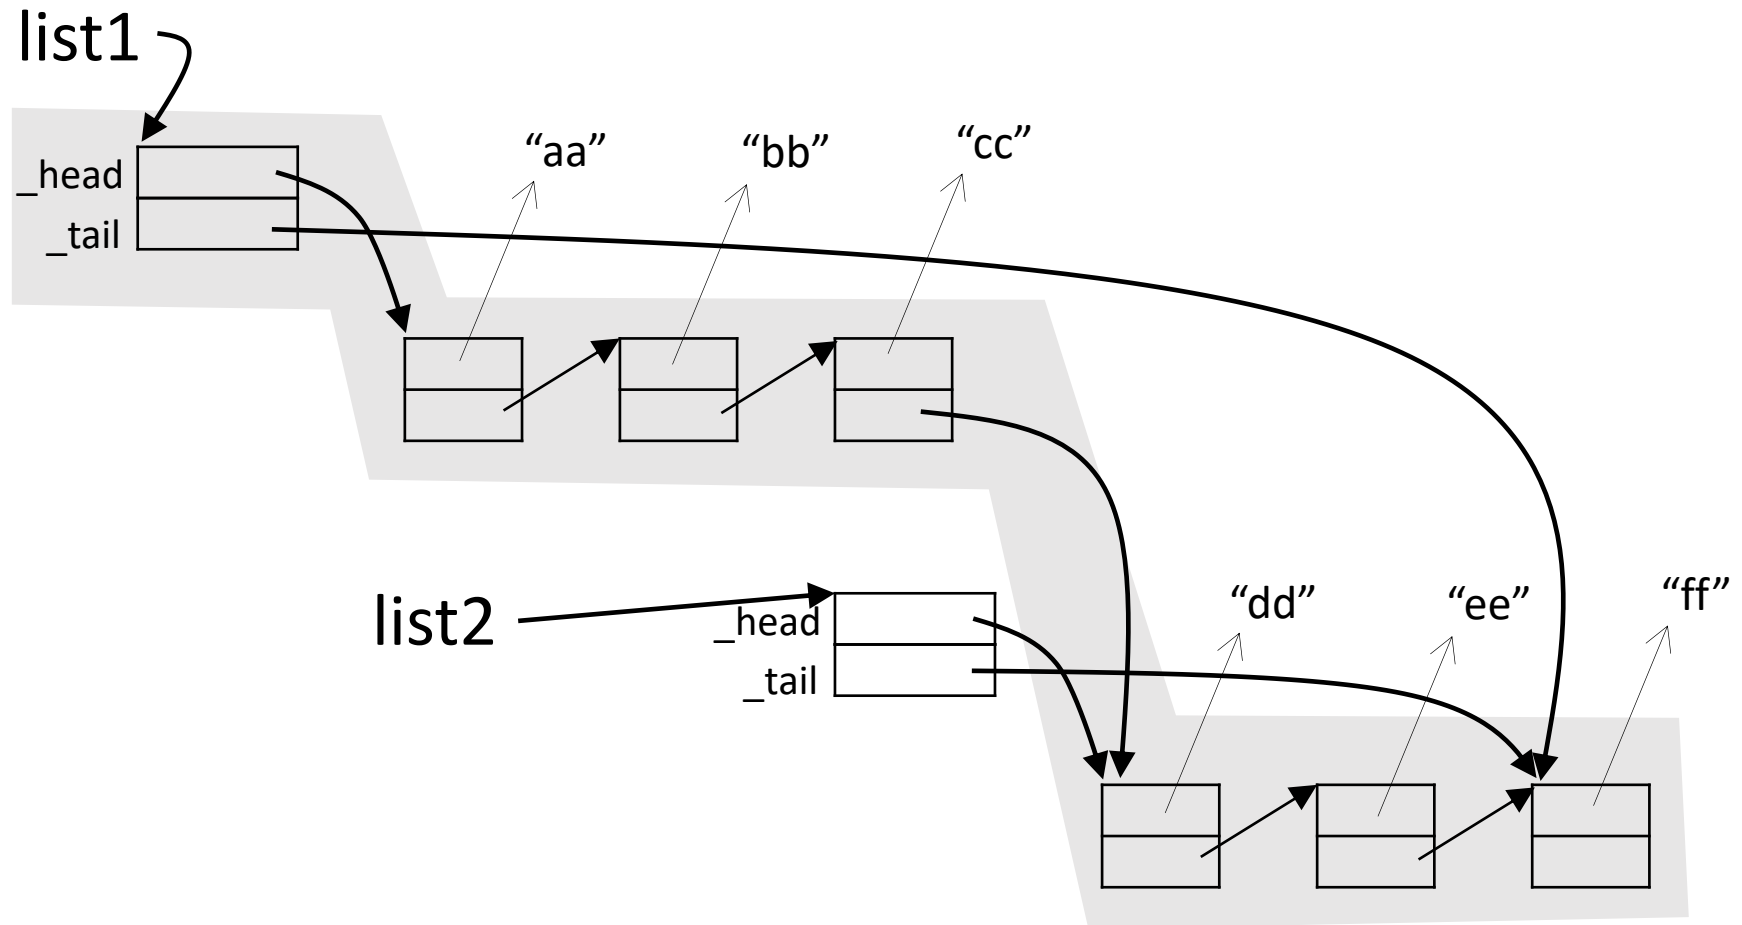

# Tail references and concatenation

# Tail references and concatenation

# Tail references and concatenation

# Maintaining a tail reference

- Concatenation and append become  $O(1)$ :

```
def concat(self, list2):  
    if self._head == None:  
        self._head = list2._head  
        self._tail = list2._tail  
    else:  
        self._tail._next = list2._head  
        self._tail = list2._tail
```

- All linked list operations must now make sure that the tail reference is kept properly updated

# Exercise-ICA-32, p.1-3

Given the following LinkedList definition:

LinkedList

```
class LinkedList:
```

```
    def __init__(self):
```

```
        self._head = None
```

```
        self._tail = None
```

Write the `append(self, new)` method for the class.

# Linked lists: summary

Operation	Without tail reference	With tail reference
add to front of list	$O(1)$	
append to end of list	$O(n)$	$O(1)$
find nth element	$O(n)$	
insert	$O(1)$ if prev. node is available $O(n)$ otherwise	
delete	$O(1)$ if prev. node is available $O(n)$ otherwise	
concatenate	$O(n)$	$O(1)$

# Some common growth-rate curves
